

**NAME**

URI::URL – Uniform Resource Locators

**SYNOPSIS**

```
$u1 = URI::URL->new($str, $base);
$u2 = $u1->abs;
```

**DESCRIPTION**

This module is provided for backwards compatibility with modules that depend on the interface provided by the `URI::URL` class that used to be distributed with the `libwww-perl` library.

The following differences exist compared to the `URI` class interface:

- The `URI::URL` module exports the `url()` function as an alternate constructor interface.
- The constructor takes an optional `$base` argument. The `URI::URL` class is a subclass of `URI::WithBase`.
- The `URI::URL->new` local class method is the same as `URI::file->new_abs`.
- **URI::URL::strict(1)**
- `$url->print_on` method
- `$url->crack` method
- `$url->full_path`: same as `($uri->abs_path || “/”)`
- `$url->netloc`: same as `$uri->authority`
- `$url->epath`, `$url->equery`: same as `$uri->path`, `$uri->query`
- `$url->path` and `$url->query` pass unescaped strings.
- `$url->path_components`: same as `$uri->path_segments` (if you don’t consider path segment parameters)
- `$url->params` and `$url->eparams` methods
- `$url->base` method. See `URI::WithBase`.
- `$url->abs` and `$url->rel` have an optional `$base` argument. See `URI::WithBase`.
- `$url->frag`: same as `$uri->fragment`
- `$url->keywords`: same as `$uri->query_keywords`
- `$url->localpath` and friends map to `$uri->file`.
- `$url->address` and `$url->encoded822addr`: same as `$uri->to` for mailto URI
- `$url->groupart` method for news URI
- `$url->article`: same as `$uri->message`
