NAME

dladdr, dladdr1 - translate address to symbolic information

LIBRARY

Dynamic linking library (libdl, -ldl)

SYNOPSIS

DESCRIPTION

The function $\mathbf{dladdr}()$ determines whether the address specified in addr is located in one of the shared objects loaded by the calling application. If it is, then $\mathbf{dladdr}()$ returns information about the shared object and symbol that overlaps addr. This information is returned in aDl_info structure:

If no symbol matching addr could be found, then dli_sname and dli_saddr are set to NULL.

The function **dladdr1**() is like **dladdr**(), but returns additional information via the argument *extra_info*. The information returned depends on the value specified in *fla gs*, which can have one of the following values:

RTLD_DL_LINKMAP

Obtain a pointer to the link map for the matched file. The *extra_info* argument points to a pointer to a *link_map* structure (i.e., *struct link_map* **), defined in<*link.h*> as:

```
struct link_map {
    ElfW(Addr) l_addr; /* Difference between the
                           address in the ELF file and
                           the address in memory */
    char
                        /* Absolute pathname where
              *1 name;
                           object was found */
   ElfW(Dyn) *1 ld;
                        /* Dynamic section of the
                           shared object */
    struct link_map *l_next, *l_prev;
                        /* Chain of loaded objects */
    /* Plus additional fields private to the
       implementation */
};
```

RTLD_DL_SYMENT

Obtain a pointer to the ELF symbol table entry of the matching symbol. The $extra_info$ argument is a pointer to a symbol pointer: $const\ ElfW(Sym)$ **. The ElfW() macro definition turns its ar gument into the name of an ELF data type suitable for the hardware architecture. For example, on a 64-bit platform, ElfW(Sym) yields the data type name $Elf64_Sym$, which is defined in <elf.h> as:

The *st_name* field is an index into the string table.

The *st_info* field encodes the symbol's type and binding. The type can be extracted using the macro **ELF64_ST_TYPE(st_info)** (or **ELF32_ST_TYPE()** on 32-bit platforms), which yields one of the following values:

| Value | Description |
|---------------|------------------------------------|
| STT_NOTYPE | Symbol type is unspecified |
| STT_OBJECT | Symbol is a data object |
| STT_FUNC | Symbol is a code object |
| STT_SECTION | Symbol associated with a section |
| STT_FILE | Symbol's name is filename |
| STT_COMMON | Symbol is a common data object |
| STT_TLS | Symbol is thread-local data object |
| STT_GNU_IFUNC | Symbol is indirect code object |

The symbol binding can be extracted from the *st_info* field using the macro **ELF64_ST_BIND(st_info)** (or **ELF32_ST_BIND()** on 32-bit platforms), which yields one of the following values:

| Value | Description | |
|----------------|---------------|--|
| STB_LOCAL | Local symbol | |
| STB_GLOBAL | Global symbol | |
| STB_WEAK | Weak symbol | |
| STB_GNU_UNIQUE | Unique symbol | |

The *st_other* field contains the symbol's visibility, which can be extracted using the macro **ELF64_ST_VISIBILITY(st_info)** (or **ELF32_ST_VISIBILITY()** on 32-bit platforms), which yields one of the following values:

| Value | Description |
|---------------|-------------------------------------|
| STV_DEFAULT | Default symbol visibility rules |
| STV_INTERNAL | Processor-specific hidden class |
| STV_HIDDEN | Symbol unavailable in other modules |
| STV_PROTECTED | Not preemptible, not exported |

RETURN VALUE

On success, these functions return a nonzero value. If the address specified in addr could be matched to a shared object, but not to a symbol in the shared object, then the $info->dli_sname$ and $info->dli_sname$ fields are set to NULL.

If the address specified in addr could not be matched to a shared object, then these functions return 0. In this case, an error message is *not* available via **dlerror**(3).

VERSIONS

dladdr() is present in glibc 2.0 and later. **dladdr1()** first appeared in glibc 2.3.3.

ATTRIBUTES

For an explanation of the terms used in this section, see **attributes**(7).

| Interface | Attribute | Value |
|---------------------|---------------|---------|
| dladdr(), dladdr1() | Thread safety | MT-Safe |

STANDARDS

These functions are nonstandard GNU extensions that are also present on Solaris.

BUGS

Sometimes, the function pointers you pass to **dladdr**() may surprise you. On some architectures (notably i386 and x86-64), *dli_fname* and *dli_fbase* may end up pointing back at the object from which you called **dladdr**(), even if the function used as an argument should come from a dynamically linked library.

The problem is that the function pointer will still be resolved at compile time, but merely point to the plt (Procedure Linkage Table) section of the original object (which dispatches the call after asking the dynamic linker to resolve the symbol). To work around this, you can try to compile the code to be position-independent: then, the compiler cannot prepare the pointer at compile time any more and gcc(1) will generate code that just loads the final symbol address from the got (Global Offset Table) at run time before passing it to dladdr().
