NAME

      debconf–show – query the debconf database

SYNOPSIS

      `debconf-show packagename [...] [--db=dbname]`
      `debconf-show --listowners [--db=dbname]`
      `debconf-show --listdbs`

DESCRIPTION

      debconf-show lets you query the debconf database in different ways.

      The most common use is ''debconf-show packagename'', which displays all items in the debconf database owned by a given package, and their current values. Questions that have been asked already are prefixed with an '*'.

      This can be useful as a debugging aid, and especially handy in bug reports involving a package's use of debconf.

OPTIONS

      −−db=*dbname*

          Specify the database to query. By default, debconf-show queries the main database.

      −−listowners

          Lists all owners of questions in the database. Generally an owner is equivalent to a debian package name.

      −−listdbs

          Lists all available databases.
